ASSIGNMENT - I

stability of complexes $Ni(CO)_4$ and $Co_2(CO)_8$ based on EAN and 18 electron rule;

$Ni(CO)_4$:

Ex: $Z =$ atomic no. of nickel $= 28$

$a =$ no. of electrons donated by terminal carbonyl groups

$b =$ no. of electrons donated by bridging carbonyl group

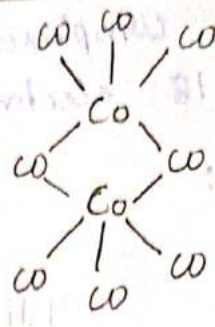

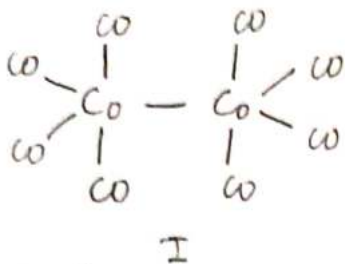

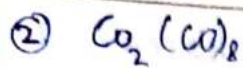

$c =$ no. of electrons donated by other metal for formation of M-M bond

$$\begin{aligned} \therefore \text{EAN OF Ni} &= Z + a + b + c \\ &= 28 + 4 \times 2 + 0 + 0 \\ &= 28 + 8 \\ &= 36 \end{aligned}$$

In order to check the validity of 18 electrons rule, put the no. of valence electrons of Nickel atom in place of its atomic number in EAN equation.

$$\begin{aligned} \therefore \text{No. of valence electrons surrounding the nucleus of the metal atom} &= \text{No. of valence electron of metal atom} + a + b + c \\ &= 10 + 8 + 0 + 0 \\ &= 18 \end{aligned}$$

Thus $Ni(CO)_4$ obeys EAN rule as well as 18 electron rule. Hence it is most stable, contains only terminal CO groups.

In str. (I),

The no. of valence electrons in cobalt = 9

The no. of electrons contributed by 4 terminal CO group = 4×2

The contribution $\text{Co}-\text{Co} = 1$

\therefore Number of valence electrons surrounding the nucleus of the metal ion

$$= \text{No. of valence electrons of metal atom} + a + b + c$$

$$= 9 + 8 + 0 + 1$$

$$= 18$$

In str. (II),

The no. of valence electrons in cobalt = 9

The no. of electrons contributed by 3 terminal CO group = 3×2

The no. of electrons contributed by bridging CO group = 2×1

\therefore Number of valence electrons surrounding the nucleus of the metal atom

$$= \text{No. of valence electrons of metal atom} + a + b + c$$

$$= 9 + 6 + 2 + 0$$

$$= 17$$

Therefore str. (I) obey 18 electrons rule but not str. (II)

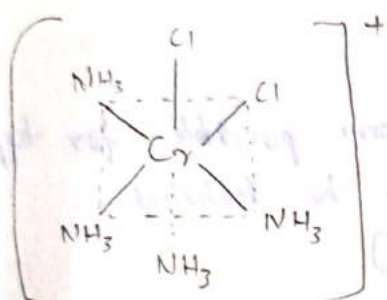

hence str. (I) is most stable.

Geometrical isomerism coordination number - 6

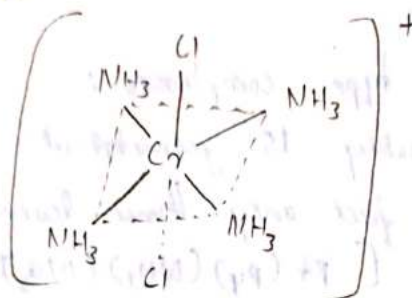

i) $[Ma_4b_2]$ type complexes:

This type of complexes exist in cis and trans isomers. In cis isomer, the two monodentate 'b' ligands occupy adjacent positions of the octahedron while in trans-isomer these ligands occupy the opposite position of the octahedron.

For example: $[Cr(NH_3)_4Cl_2]^+$

cis form

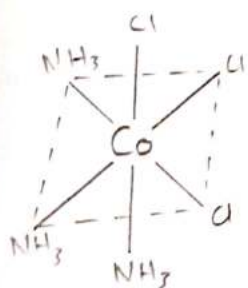

trans form

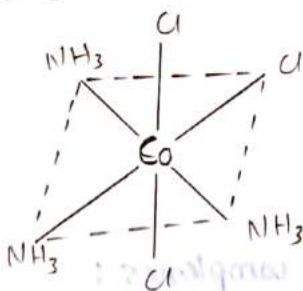

ii) $[Ma_3b_3]$ type complexes:

This type of complexes exist in cis & trans isomers. cis form the identical ligands occupy the corners of one of the triangular faces of octahedral but not in trans form.

For example: $[Co(NH_3)_3Cl_3]$

cis form

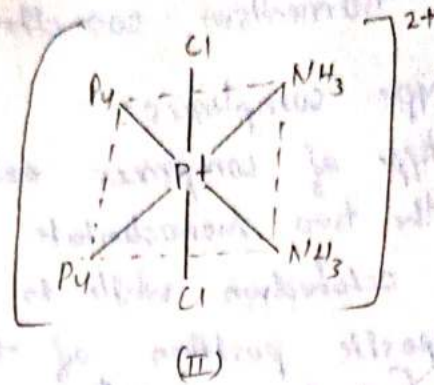

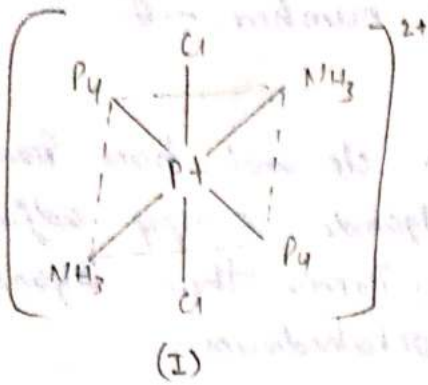

trans form

iii) $[Ma_2b_2c_2]$ type complexes:

This type of complexes can exist theoretically in geometrical forms out of these only three have been prepared. ~~All the five isomers~~

For example: $[Pt(NH_3)_2(PY)_2Cl_2]^{2+}$

iv) $[Mabcdef]$ type complexes :

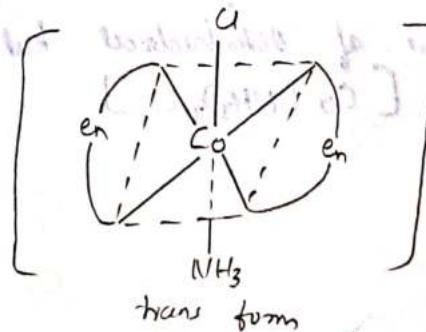

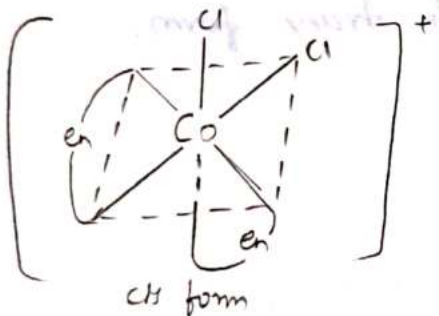

Theoretically 15 geometrical isomers are possible for $t_2g e_g$ of complexes. In fact only three isomers have been isolated.

For example : $[Pt(Py)(NH_3)(NO_2)(Cl)(Br)(I)]$

v) $[M(AA)_2 a_2]$ type complexes :

Here 'AA' represents a symmetrical bidentate ligand. In $t_2g e_g$ AA are two identical donor atoms. octahedral complexes

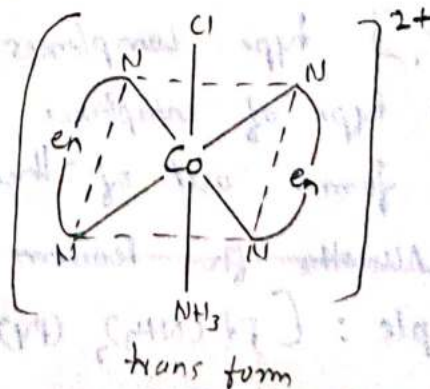

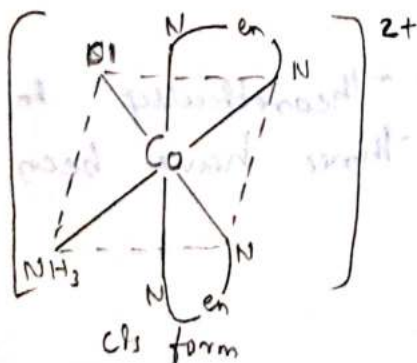

For example : $[Co(en)_2 Cl_2]^+$

vi) $[M(AA)_2 ab]$ type complexes :

This type of complexes give cis & trans isomers.

For example : $[Co(en)_2(NH_3)Cl]^{2+}$

2) Preparation of glycerol from fats.

Glycerol occurs in many natural fats and oil in the form of glyceryl esters of long chain acids. Hydrolysis of these fats or oils with sodium hydroxide gives sodium salts of fatty acids and glycerol.

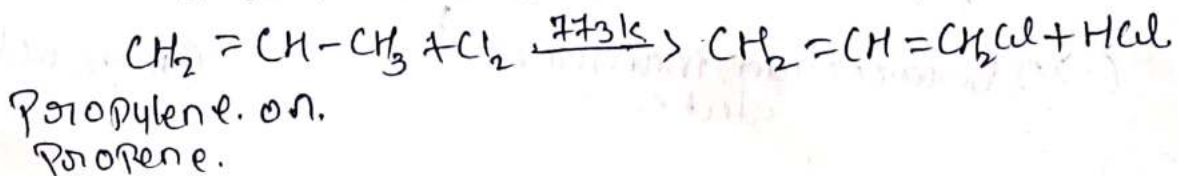

The process of hydrolysis of fats & oils is also known as saponification.

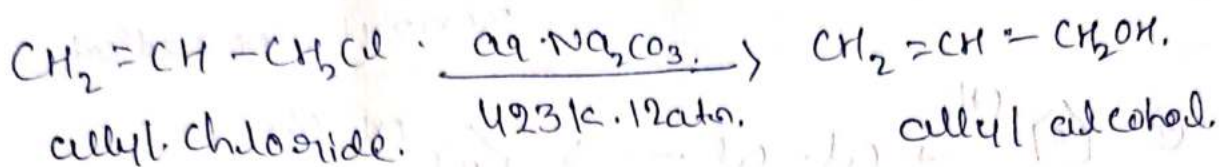

Glycerol can also be obtained from fats or oils by transesterification with methyl alcohols in the presence of methyl esters of acids of glycerol.

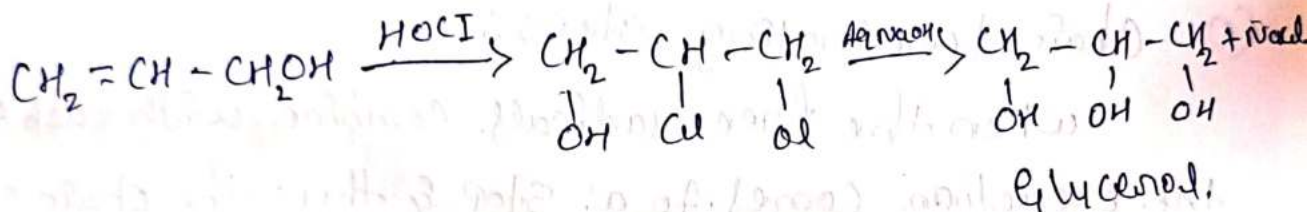

2) Preparation of glycerol from petroleum product. Glycerol is prepared synthetically from propylene which is obtained by the cracking of petroleum. The various steps taking place in the process are

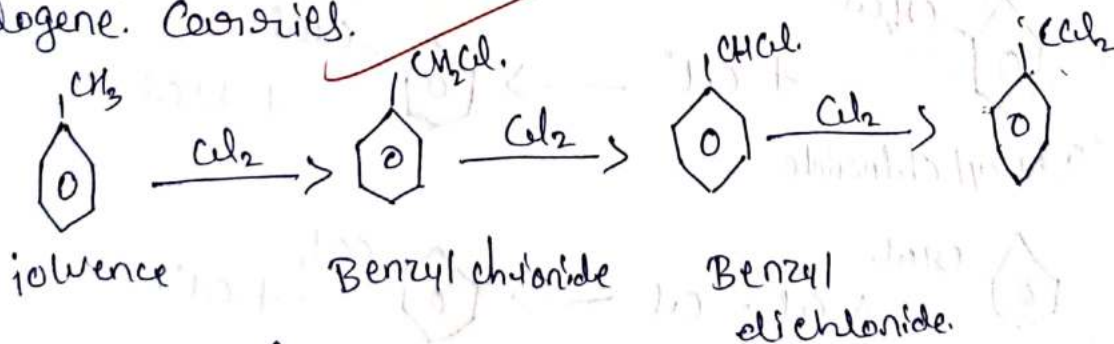

The allyl chloride is converted into allyl alcohol by hydrolyzing with aqueous sodium carbonate at 423 K. & at a pressure of 12 atmospheres.

Allyl alcohol is then treated with hypochlorous acid (HOCl) to give to chloro hydrin from which glycerol is obtained by treatment with sodium hydroxide.

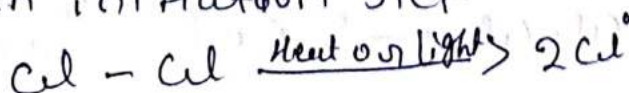

3) The reaction in which one or more ~~the~~ hydrogen of benzene or the side chain are replaced by the atoms is called side chain halogenation. It can be brought about by treating an arene with a halogen in the presence of light or heat & the absence of halogen carrier.

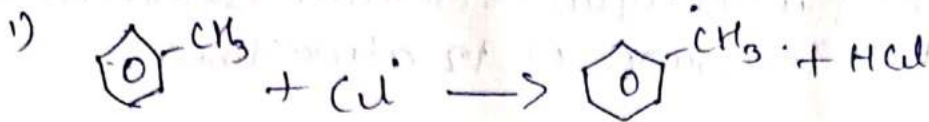

Mechanism of halogenation side chain halogenation of toluene occurs by a free radical mechanism as given below.

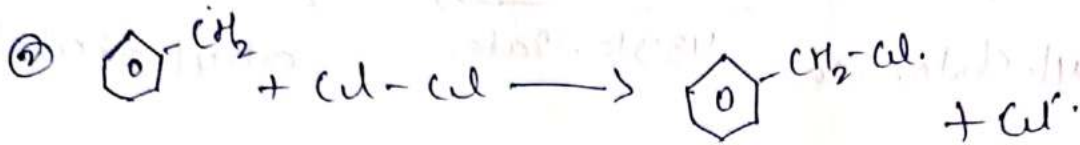

(a) Chain initiation step.

b) Chain propagation steps.

Benzyl free radical

Benzyl chloride

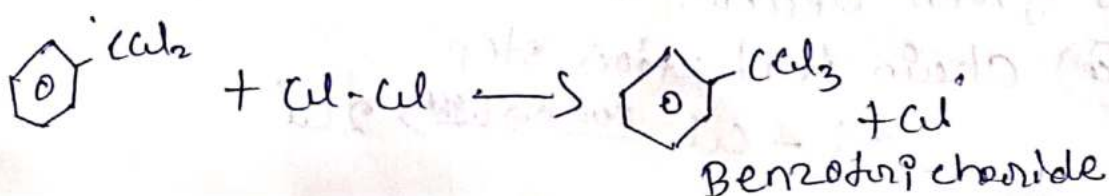

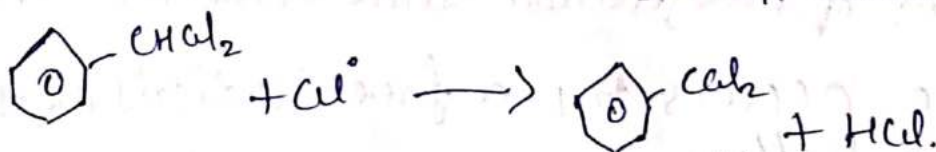

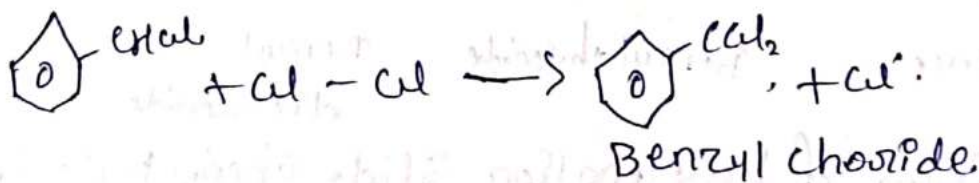

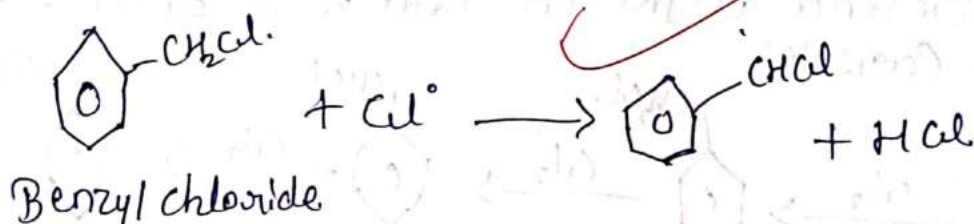

The above step (1) & (2) are repeated again & again

c) Chain terminating steps:

when the free radicals combine with each other the reaction comes to a stop & thus the chain of reaction gets terminated

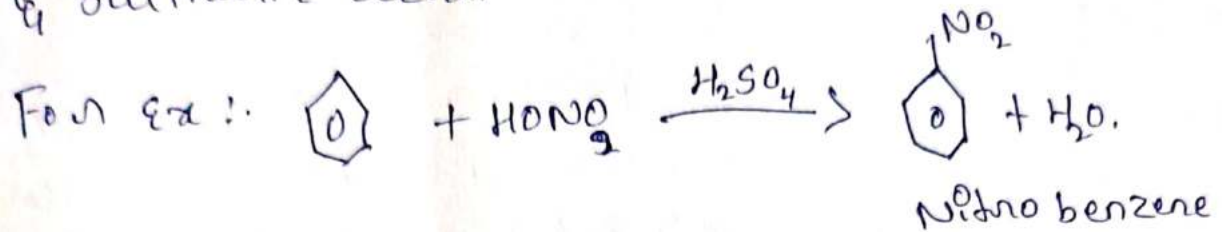

when excess of chlorine is used other hydrogen atoms are also replaced in the same manner this

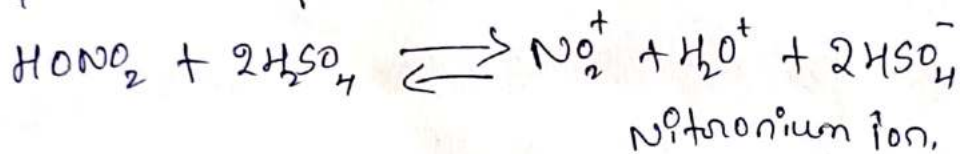

4) Benzene has a tendency to give electrophilic substitution reactions because of the π electron above & below benzene ring.

Nitration: This reaction involves the treatment of an aromatic compound with a mixture of nitric acid & sulphuric acid.

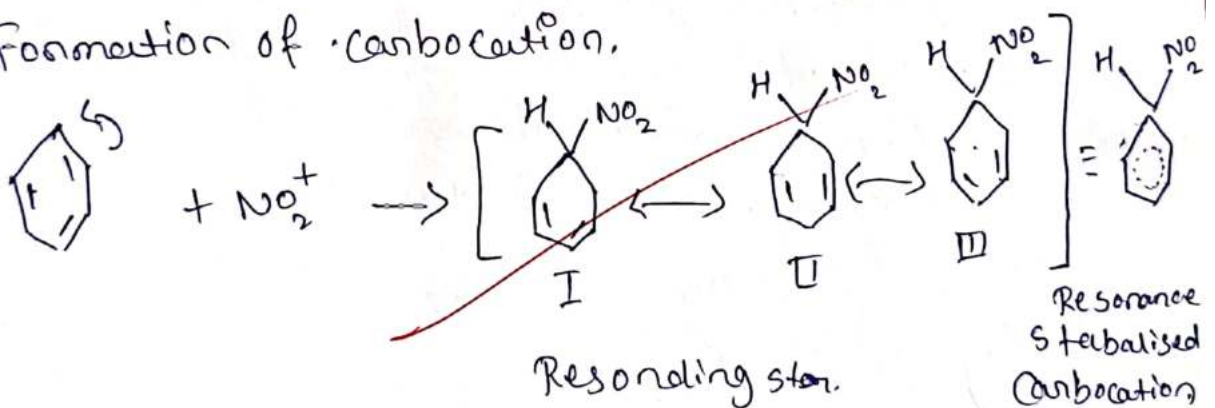

Mechanism: The various steps in the nitration of benzene can be outlined, as below.

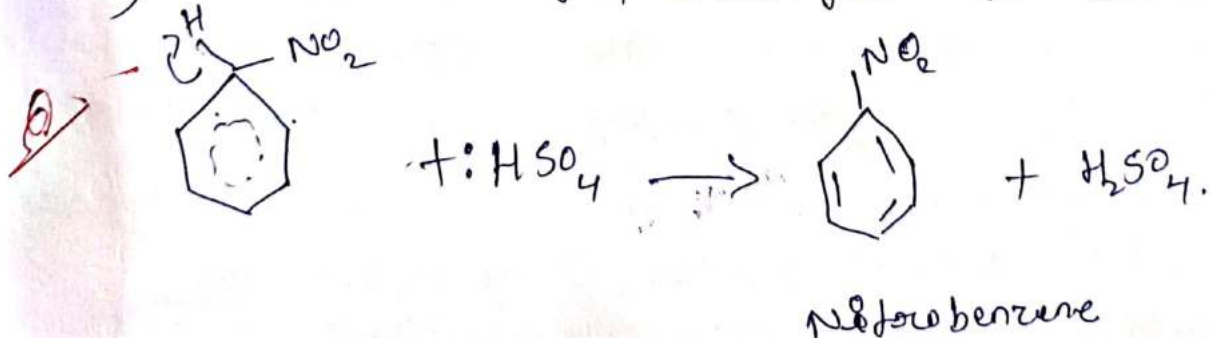

(I) Generation of electrophile.

(II) Formation of carbocation.

(III) Abstraction of proton from the carbocation
