Life cycle of Fasciolopsis buski

It is commonly known as intestinal fluke and found in digestive tract of man, sheep and pig. It is distributed from China to India. The intermediate host of these parasite are fresh water snails.

Life cycle:

The eggs after fertilization stay in the uterus for some time which later reach the bile duct. Then in the intestine of the host and finally passes out with the

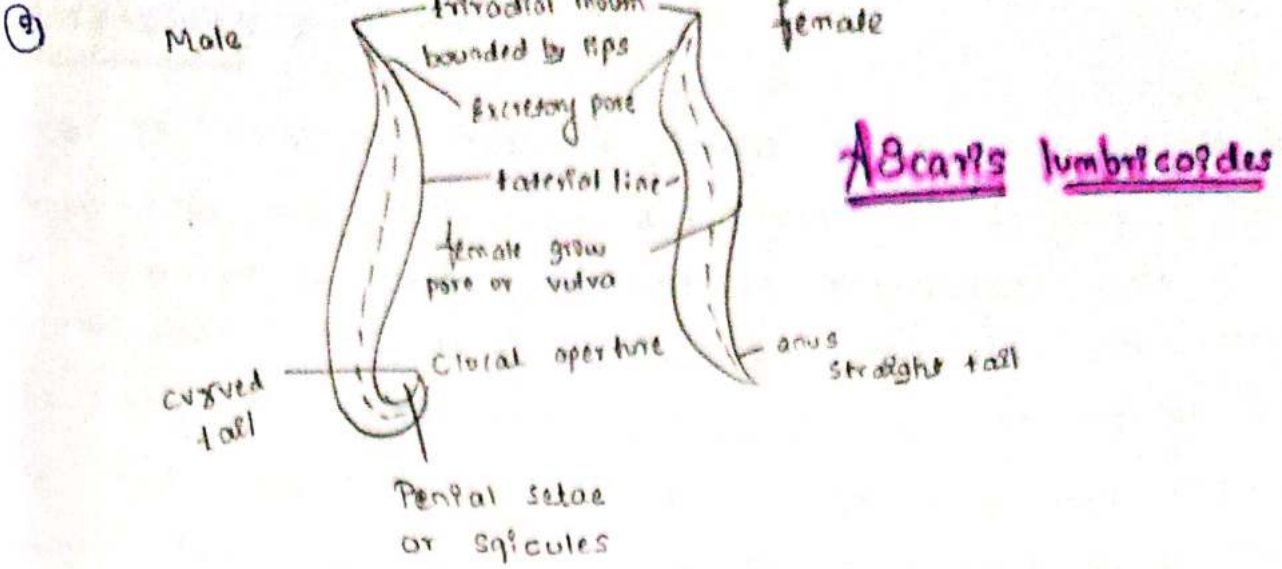

Focus under suitable condition the eggs are hatched into ciliated larva called miracidium larvae, which swim in search of suitable host that is snail and enter its pulmonary sac after 8 day miracidium forms sporozoites from which 3-8 redia larvae are found now this redia enter the intestine of these snail and produce more redia from each daughter redia other larvae form Cercariae from the Cercaria larvae form Cercariae which provide with slender tail, sucker and intestine burrow this snail and come out of the snail body how they start swimming attached to self with grass and leafy losses it's pair get encysted and form the metacercaria which enters the canal of this sheep at the time of water drinking or grazing the grasses. In the canal of their sheep cyst desolts and metacercaria reaches the intestine by burrowing develops into adult state which takes about 3 months.

Disease :-

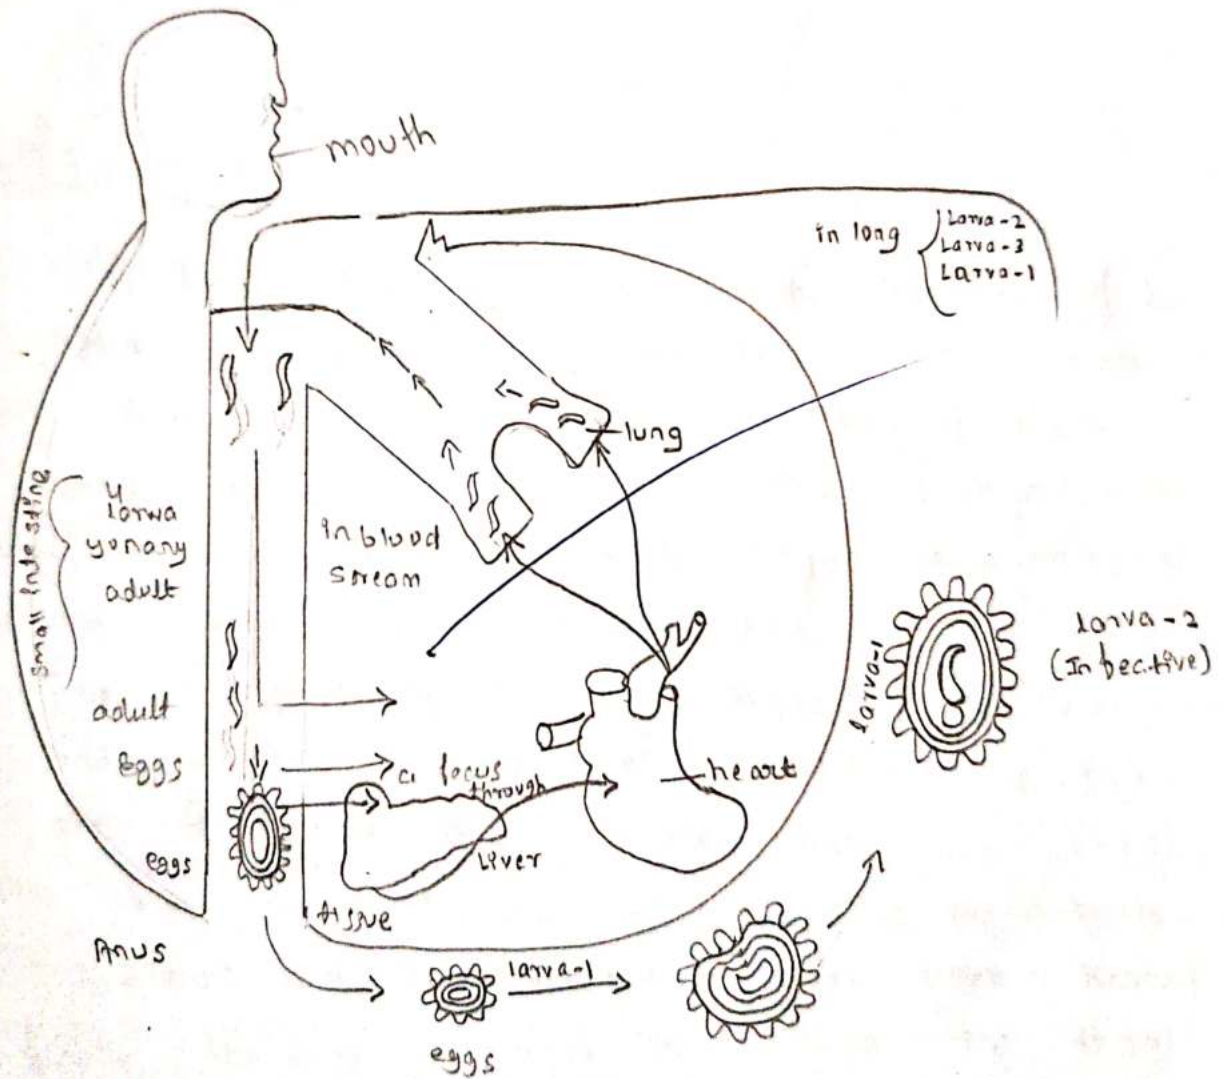

The adult worm causes erosion of the lining of the digestive tract resulting in the bleeding and pain in the intestine & proper treatment is host given the bleeding is followed by vomiting and diarrhea.

Prevention and Control :-

Use the proper cooked snail and vegetable anthelmintic drugs and crystaloids should be used for treatment.

Life cycle of Ascaris lumbricoides

47 Advantages and disadvantages of molecular Diagnosis

Advantages

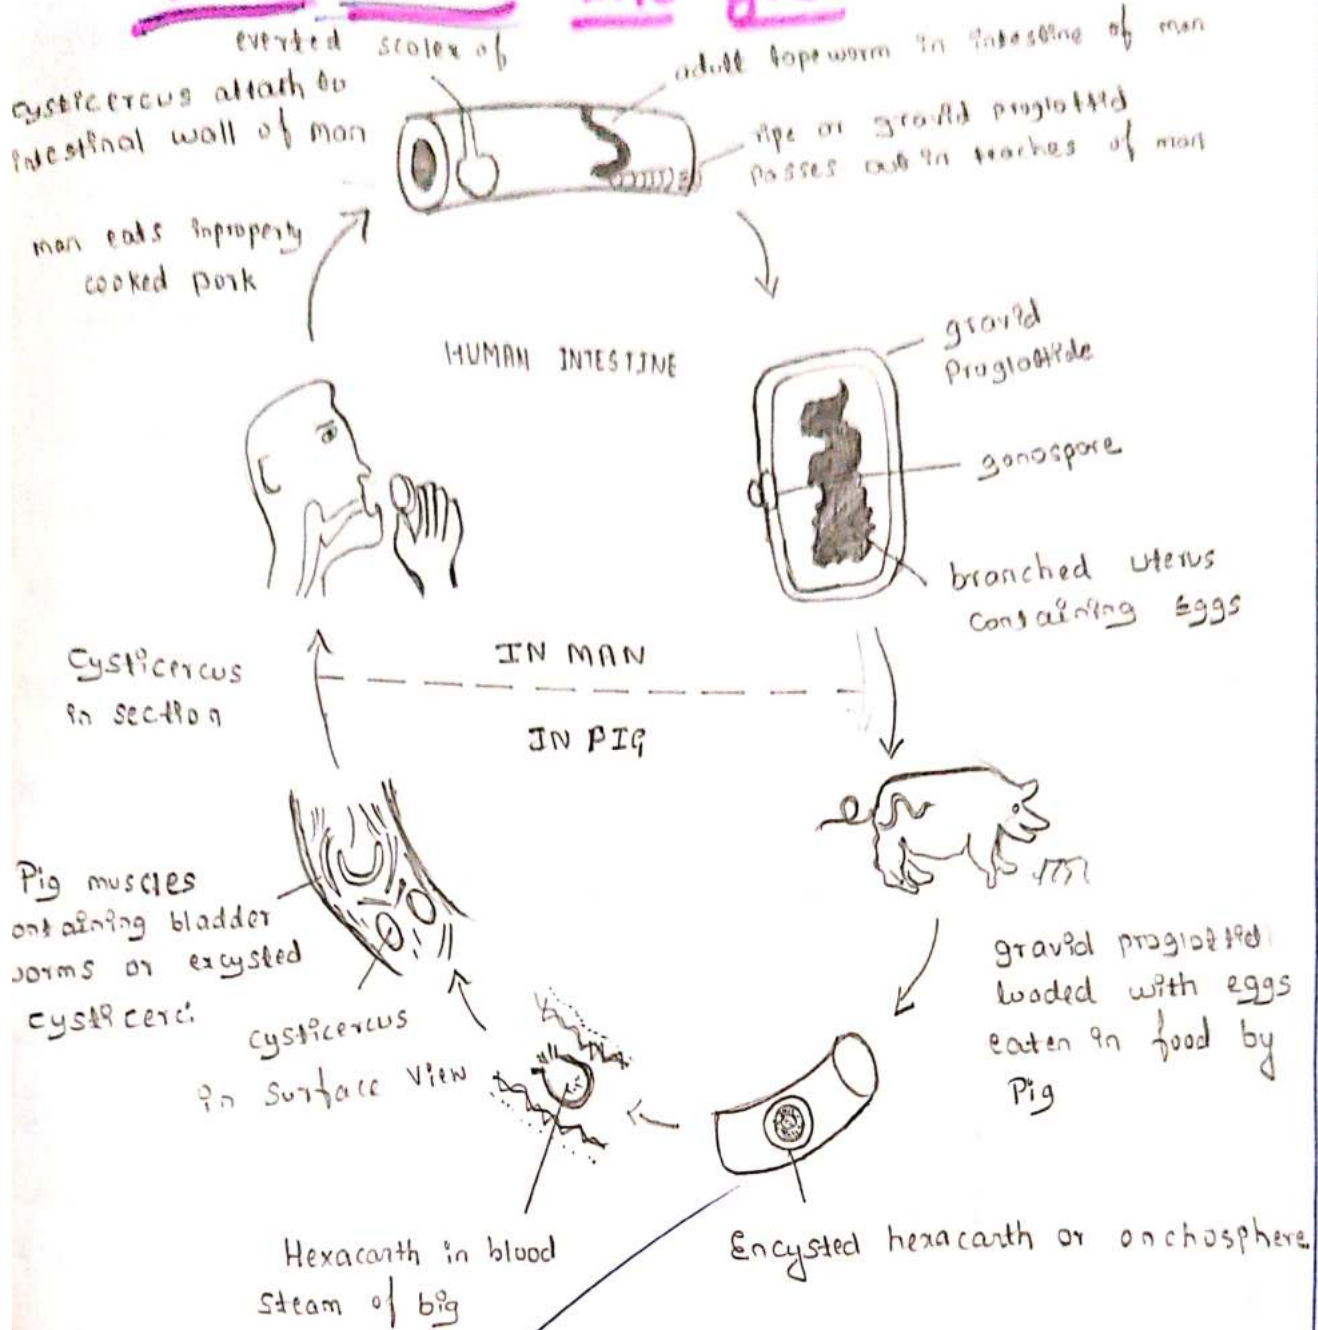

- High Sensitivity
- Can theoretically detect the presence of a single organism.
- High Specificity
 - Can detect specific genotypes
 - Can determine drug resistance
 - Can predict virulence
- Speed
 - Quick than traditional culturing for certain organisms
- Simplicity
 - Some assays are now automated.

Disadvantages

- Expensive
 - So specific that must have good clinical data to support infection by that organism before testing is initiated.
 - May be a problem with mixed cultures - would have to assay for all organisms causing the infection.
- Too Sensitive less clinical value.
- Will miss new organisms unless seq sequencing is done as we will be doing in the lab for our molecular unknowns (not practical in a clinical setting).

51

Tenia Solium Life cycle

It is commonly called as the pork tapeworm and found in the small intestine of man, where pork is consumed much as food, *Tenia Solium* is found as an endoparasite. Its intermediate is found in abundance in China, Germany, India. *Solium* is white in colour & its body is elongated differentiated into scolex next

and the scolex beared fork suckers and worm keeps in self attach with the of elementary absorb the digested food of host elementary canal.

Life cycle :-

Cell fertilization take place within the same proglotid and the rip proglotid containing fertilization egg cell detached from the body of the tape worm and passes out of the host body in formal chain with the faeces, These fertilized eggs is taken by the pigs along with the faeces reach the intestine of pigs where they are hatched into hatched embryos then they intestinal wall & reach muscles of the pig through blood stream in the muscles they grow and found cysticercus larve which are still covered with the bladder is cooked ~~part~~ taken by man the cysticercus larve reach elementary Canal and developed then the hooks and suckers.

Disease ? It caused due to worm followed by abdominal pain, anorexia, indigestion, diarrhea, eosinophilia etc.

Prevention and Control :-

The prevention needs the injection of properly cooked pore the tapeworms can be controlled by the use of hydrochloride and albendazole.

ZOOLOGY ASSIGNMENT

NAME : Santosh . k. Gavada

STD : Bsc IInd Sem

SUB : Zoology

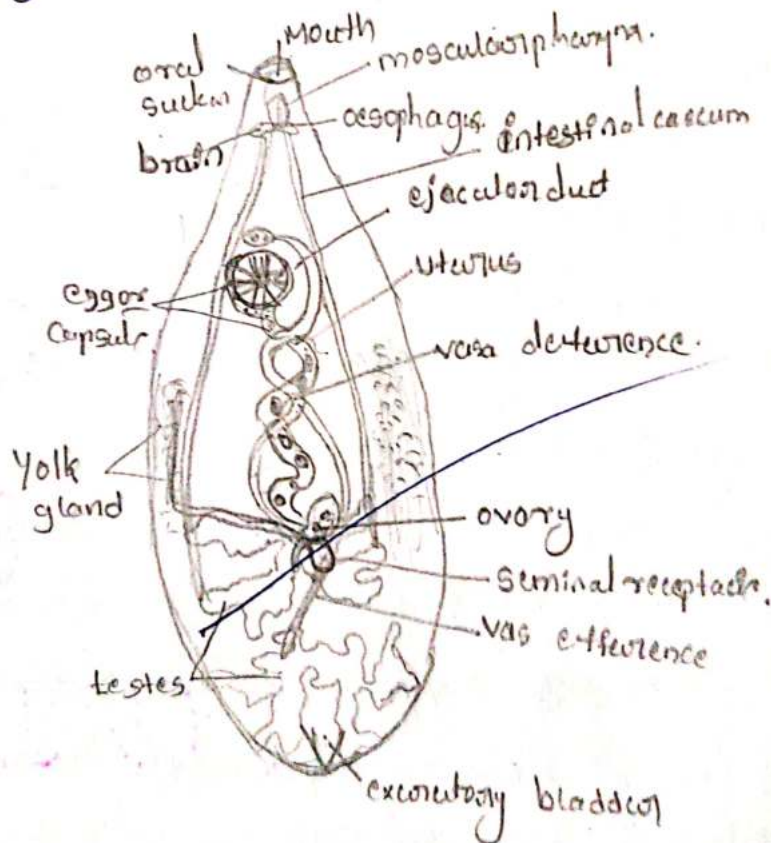

ROLL.NO : W02JS2150001

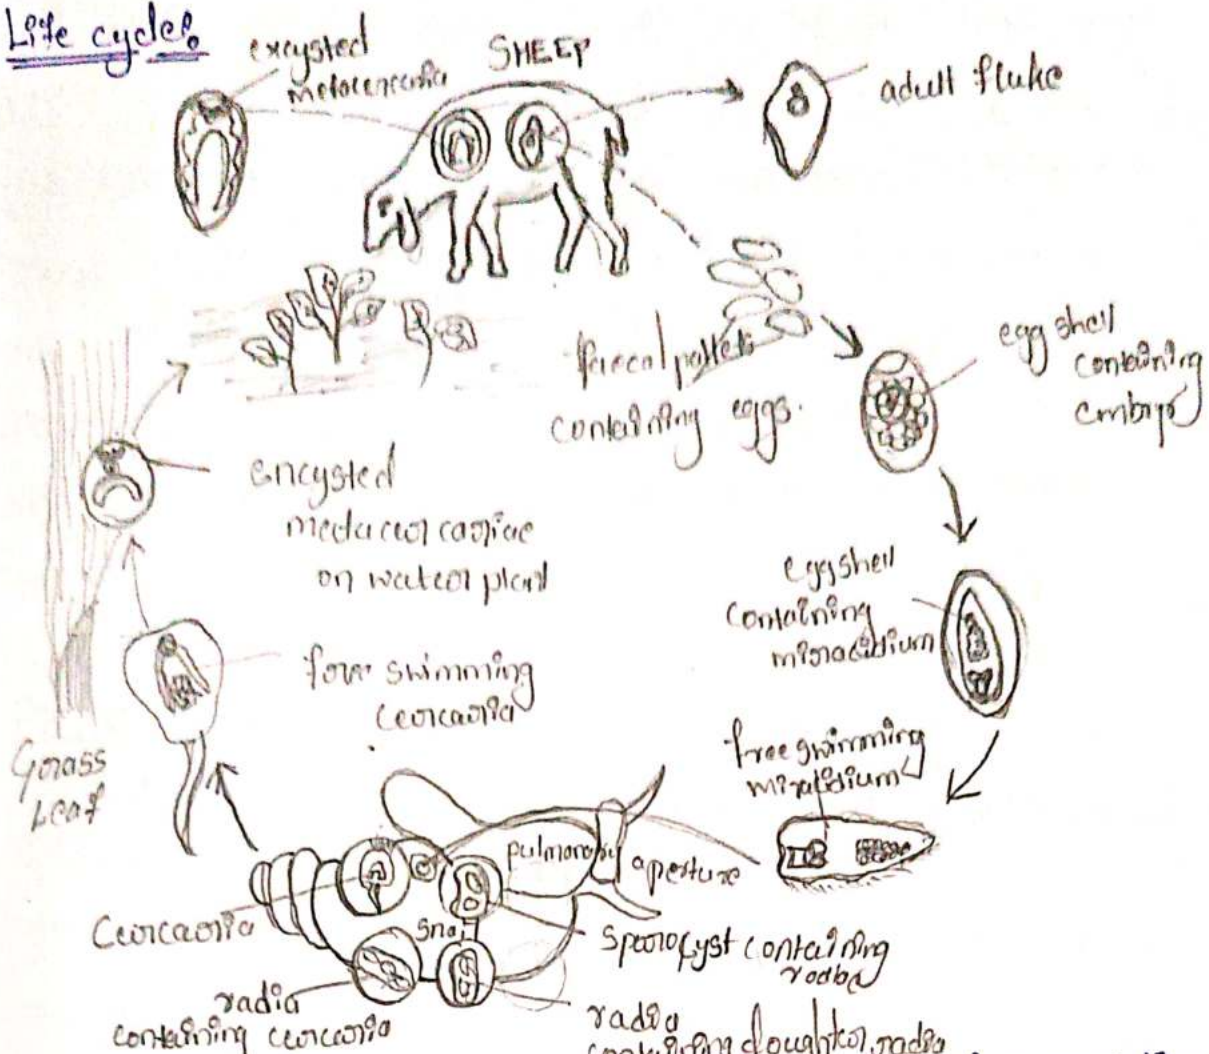

Fasciolopsis buski :-

Morphology :-

It is commonly known as the 'intestinal fluke' and found in the digestive tract of man and pig. It was distributed from China to India. The intermediate hosts of this parasite are fresh water snails. They have a cut, fleshy body. The oral sucker is subterminal & ventral. The ventral sucker is larger & a little behind the oral sucker. The genital pore is just in front of ventral sucker. The excretory pore is at hind end. The alimentary canal consists of oral sucker, small muscular pharynx, short oesophagus & a pair of long wavy non-diverticulate intestinal caeca.

Life cycle

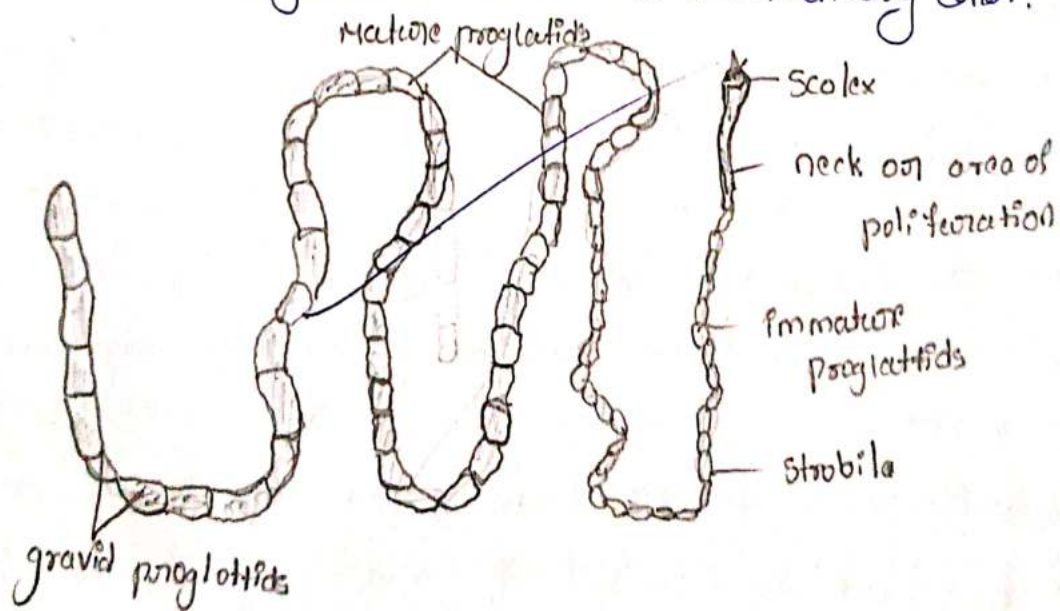

The eggs after fertilization stay in the uterus for some time which later which the oviduct. then in the intestine of the host & finally passes out with the faeces under suitable condⁿ then the eggs are hatched into ciliated larvae called miracidium larvae which swim in search of suitable host that is snail & enter permanently sac after 8 days miracidium forms sporocysts from which 3 to 8 radiae larvae are found now this radiae enter the intestine of the snail & produced more radiae (daughter radiae) from each daughter radiae other larvae cercaria's found the cer-
-caria larvae which is provided with slender tail stroke & intestine branches. the snail & come out of the

Taenia Solium (Tape worm)

Morphology

It is commonly called as the 'pork Tapeworm' and found in the small intestine of man. It is cosmopolitan in distribution. Countries where pork is consumed much as food. *T. solium* is found in an endemic form. Its infection is found in abundance in China, Germany, India. *T. solium* is white in colour. Its body is elongated, flattened & ribbon-like & differentiated into scolex, neck & strobila. The scolex bears 4 suckers & two rows of retractile hooks. Each proglottid is hermaphroditic. The alimentary canal is absent. The life cycle is complicated & involves a primary host (man) & intermediate host (pig). With the help of hooks & suckers the worm keeps itself attached with the mucosa on alimentary canal & absorbs the digested food of host's alimentary canal.

Hard Tick (Ixodidae)

The cattle tick mainly attacks the cattle but is also found on horses, mules, deer, goats & sheep. They spread cattle fever, tick fever, Texas fever from sick individuals to healthy ones. The symptoms of tick fever are high fever, reddish discoloration of urine, enlargement of spleen, loss of flesh, arched back & drooping ears.

Morphology

After maturity the female cattle tick attains a length of about 1/180 cm. It is olive-green to bluish gray in colour. They are bean-shaped with hard and wrinkled skin. The larvae are smaller provided with 3 pairs of legs whereas nymphs & adult have 4 pairs of legs.

Life cycle

The female after mating lays eggs in the soil, cracks & crevices of buildings. A single female lays about 2000 eggs in clusters. The eggs hatch into six legged larva after 2-6 weeks. The larva attaches itself on a host. These larvae start feeding, get changed into young nymphs.

which attain adult stage feeding on the same host cattle. The adults exist in two phases i.e. parasitic & non parasitic phase. Part of the life time of an adult - larva, egg stage, & most of the seed tick stage comes under non parasitic phase. - Single lifecycle. needs about 60 days & 4 years - Hens have been recorded in one year.

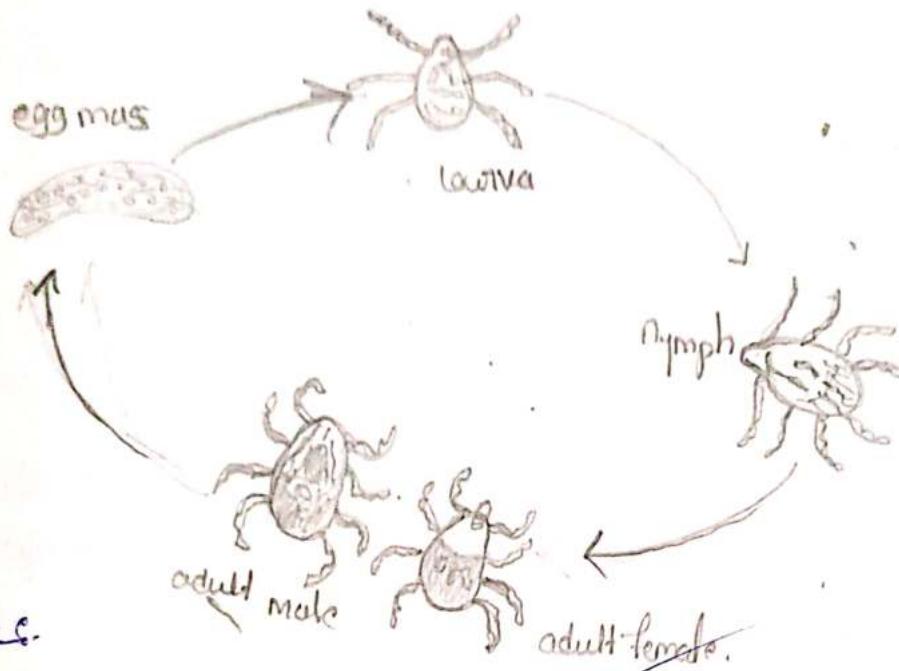

image.

The soft part of host cattle is attacked by cattle tick. Mostly they attack the skin of ear & under the base of the tail.

Prevention & control

Ticks should be removed by hand picking killed immediately.

The animals affected should be sprayed by lindane dust or carbaryl malathion 1 per cent

Dairy cattle should be dipped in 0.175 to 0.19 per cent dieldrin or trioxide.

The quarantine activities should be maintained by the Government.
